

B2B Sales Pipeline Analysis – Project Overview

B2B Sales Pipeline Analysis

SQL & Power BI

Project Scenario

Business Background

A fictional B2B technology company sells computer hardware products to business customers through a team of sales agents operating across multiple regional offices.

The company records information about its sales opportunities, including the customer account, product, sales agent, opportunity stage, engagement date, close date and deal value. Additional information is available about customer accounts, products and the sales team.

Management wants to better understand the company's sales pipeline and determine where there may be opportunities to improve sales performance.

Business Objective

The objective of this analysis is to evaluate sales pipeline performance and provide **data-driven insights and recommendations** to support management decision-making.

The analysis focuses on four key areas:

- **Regional Performance** - How does sales performance differ between regional offices?
- **Sales Agent Performance** - Which agents are generating strong sales and opportunity volumes, and what might contribute to their performance?
- **Product Performance** - Which products are driving sales, and what factors explain differences in product performance?
- **Time & Pipeline Performance** - How does sales performance change over time, and does a high volume of opportunities consistently result in higher sales?

Key Business Questions

Management would like answers to the following questions:

1. Which regional offices are generating the highest, and where may there be opportunities for improvement?
2. Which sales agents are generating the greatest sales and opportunity volumes?
3. Are differences in product sales driven primarily by opportunity volume, win rates or deal values?
4. Are there periods where a high number of opportunities does not translate into high sales?
5. What practical actions could the business investigate based on the findings?

Analytical Approach

To address these questions, the sales data was:

1. Checked and validated data using SQL
2. Explored to identify trends and differences in performance
3. Analysed across different regions, sales agents, time periods and products
4. Used to calculate key performance measures such as sales, won deals, opportunities, win rates and average won deal values
5. Presented through an interactive Power BI dashboard
6. Used to develop business insights and recommendations

Project Outputs

This project consists of:

1. SQL analysis – Data validation, standardization and exploratory analysis
2. Power BI dashboard – Interactive analysis of sales pipeline performance
3. Business insights and recommendations – Key findings identified from the analysis
4. Supporting project document – Explanation of the business scenario and analytical approach.
